ABSTRACT

In this paper, we study some transitivity action properties of the alternating group $A_n(n=4,5,6,7)$ acting on unordered and ordered pairs from the set $X = \{1,2,\dots,n\}$ through determination of the number of disjoint equivalence classes called orbits. when $n \leq 7$, the alternating group acts transitively on both $X^{(4)}$ and $X^{[4]}$.

key words : Orbits ,alternating group A_n , A_n on unordered and ordered quadruples from the set X .

1.Preliminaries

In 1964, Higman [2] introduced the rank of a group when he worked on finite permutation groups of rank 3.

In 1970, he calculated the rank and subdegrees of the symmetric group S_n acting on 2-elements subsets from the set $X = \{1,2,\dots,n\}$. He showed that the rank is 3 and the subdegrees are $1, 2(n-2), \binom{n-2}{2}$.

In 1972, Cameron [1] worked on suborbits of multiply transitive permutation groups and later in 1974, he studied suborbits of primitive groups.

In 1999 Rosen [6] dealt with the properties arising from the action of a group on unordered and ordered pairs. Based on these results we investigate some properties of the action of A_n on $X^{(4)}$, the set of all unordered quadruples from the set $X = \{1,2,\dots,n\}$ and on $X^{[4]}$, the set of all ordered quadruples from $X = \{1,2,\dots,n\}$. Let $G = A_n$ act naturally on X , then G acts on $X^{(4)}$ by the rule $g\{a,b,c,d\} = \{ga,gb,gc,gd\} \forall g \in G$ and $\{a,b,c,d\} \in X^{(4)}$ and on $X^{[4]}$

1.1 NOTATION AND TERMINOLOGIES

In this paper, we shall represent the following notations as: \sum_i –sum over i ; $\binom{m}{n}$ – m combination n ; S_n – Symmetric group of degree n and order $n!$; A_n –an alternating group of degree n and order $\frac{n!}{2}$; $|G|$ – The order of a group G ; $|G:H|$ – Index of H in G ; $X^{(4)}$ – The set of an unordered quadruples from set $X = \{1,2,\dots,n\}$; $X^{[4]}$ – The set of an ordered quadruples from set $X = \{1,2,\dots,n\}$; $\{a,b,c,d\}$ – Unordered quadruple; $[a,b,c,d]$ – Ordered quadruple . We also define some basic terminologies on permutation group and give some results on group actions as:

Definition 1.1.1:

Let X be a non-empty set. A permutation of X is a one-to-one mapping of X onto itself.

Definition 1.1.2:

Let X be the set $\{1,2,\dots,n\}$, the symmetric group of degree n is the group of all permutations of X under the binary operation of composition of maps. It is denoted by S_n and has order $n!$.

Definition 1.1.3:

A permutation of finite set is even or odd according to whether it can be expressed as the product of an even or odd number of 2-cycles (transpositions).

Definition 1.1.4: The subgroup of S_n consisting of all even permutation in S_n is called the alternating group. It is denoted by A_n and $|A_n| = \frac{n!}{2}$.

Definition 1.1.5: Let X be a non-empty set. The group G acts on the left of X if for each $g \in G$ and each $x \in X$ there corresponds a unique element $gx \in X$ such that;

- i) $(g_1g_2)x = g_1(g_2x) \forall g_1, g_2 \in G$ and $x \in X$.
- ii) For any $x \in X, Ix = x$, where I is the identity in G

The action of G from the right on X can be defined in a similar way. In fact it is merely a matter of taste whether one writes the group element on the left or on the right.

Definition 1.1.6

Let G act on a set X and let $x \in X$. The stabilizer of x in G , denoted by $\text{stab}_G(x)$, is the set of all elements in G which fix x i.e. $\text{stab}_G(x) = \{g \in G | gx = x\}$.

Note This set is also denoted by G_x . $\text{Stab}_G(x)$ is a subgroup of G , that is; $\text{stab}_G(x) \leq G$.

Definition 1.1.7

Let G act on a set X . The set of elements of X fixed by $g \in G$ is called the fixed point set of G , denoted by $\text{Fix}(g)$. Thus, $\text{Fix}(g) = \{x \in X | gx = x\}$.

Definition 1.1.8

If a finite group G acts on a set X with n elements, each $g \in G$ corresponds to a permutation σ of X , which can be written uniquely as a product of disjoint cycles. If σ has α_1 cycles of length 1, α_2 cycles of length 2, ..., α_n cycles of length n , we say that σ and hence g has cycle type $(\alpha_1, \alpha_2, \dots, \alpha_n)$.

Definition 1.1.9

If the action of a group G on a set X has only one orbit, then G is said to act transitively on X . In other words, a group G acts transitively on X if for every pair of points $x, y \in X$, there exists $g \in G$ such that $gx = y$.

Definition 1.1.10

Let G act on a set X . Then G is said to act doubly transitively on X if for every two ordered pairs (x_1, x_2) and (y_1, y_2) of distinct elements in X , there exists $g \in G$ such that $gx_1 = y_1$ and $gx_2 = y_2$.

Theorem 1.1.13 [Krishnamurthy 1985, p.68]

Two permutations in A_n are conjugate if and only if they have the same cycle type; and if $g \in A_n$ has cycle type $(\alpha_1, \alpha_2, \dots, \alpha_n)$, then the number of permutations in A_n conjugate to g is $\frac{n!}{\prod_{i=1}^n \alpha_i! i^{\alpha_i}}$.

Theorem 1.1.14 [Orbit- Stabilizer Theorem –Rose 1978, p.72]

Let G be a group acting on a finite set X and $x \in X$. Then $|\text{Orb}_G(x)| = [G:\text{Stab}_G(x)]$.

Theorem 1.1.15 [Cauchy- Frobenius Lemma-Rotman 1973, p.45]

Let G be a group acting on finite set X . Then the number of G -orbits in X is $\frac{1}{|G|} \sum_{g \in G} |\text{Fix}(g)|$.

This theorem is usually but erroneously attributed to Burnside (1911) cf. Neumann (1977).

1.2 INTRODUCTION

2.ACTION OF THE ALTERNATING GROUP A_n ON UNORDERED QUADRUPLES

2.1 some general results of permutation groups acting on $X^{(4)}$

We first give two the proofs of two lemmas which will be useful in the investigation of transitivity of the action of A_n on $X^{(4)}$

Lemma 2.1.1

Let the cycle type of $g \in A_n$ be $(\alpha_1, \alpha_2, \dots, \alpha_n)$. Then the number of elements in $X^{(4)}$ fixed by g is given by the formula $|\text{Fix}(g)| = \binom{\alpha_1}{4} + \binom{\alpha_1}{2} \binom{\alpha_2}{1} + \binom{\alpha_2}{2} + \alpha_1 \alpha_3 + \alpha_4$.

Proof

Let $\{a, b, c, d\} \in X^{(4)}$ and $g \in A_n$. Then g fixes $\{a, b, c, d\}$ if and only if g permutes the elements in the set $\{a, b, c, d\}$ as in the following cases;

Case 1:

Each of the elements a, b, c and d comes from a single-cycle in g . In this case the number of unordered quadruples fixed by g is $\binom{\alpha_1}{4}$, for $\alpha_1 \geq 4$.

Case 2:

Two of the elements a, b, c and d come from single-cycles and the other two elements come from a 2-cycle, say $(ab)(c)(d) \dots$. In this case the number of unordered quadruples fixed by g is $\binom{\alpha_1}{2} \binom{\alpha_2}{1}$, for $\alpha_1 \geq 2$, and $\alpha_2 \geq 1$.

Case 3:

Each of the elements a, b, c and d come from a 2-cycle in g , say $(ab)(cd) \dots$. In this case the number of unordered quadruples fixed by g is $\binom{\alpha_2}{2}$, $\alpha_2 \geq 2$.

Case 4:

Three of the elements a, b, c and d come from a 3-cycle and one element comes from a single-cycle say $(abc)(d) \dots$. In this case the number of unordered quadruples fixed by g is $\alpha_1 \alpha_3$.

Case 5:

The elements a, b, c and d come from a 4-cycle in g say $(abcd) \dots$. In this case the number of unordered quadruples fixed by g is α_4 . Thus the total number of unordered quadruples fixed by g is $\binom{\alpha_1}{4} + \binom{\alpha_1}{2} \binom{\alpha_2}{1} + \binom{\alpha_2}{2} + \alpha_1 \alpha_3 + \alpha_4$. ■

Lemma 2.1.2

Let $g \in A_n$ have cycle type $(\alpha_1, \alpha_2, \dots, \alpha_n)$. Then the number of permutations in A_n that fix $\{a, b, c, d\} \in X^{(4)}$ and having the same cycle type as g is given by

$$\frac{(n-4)!}{1^{\alpha_1-4}(\alpha_1-4)! \prod_{i=2}^n \alpha_i! i^{\alpha_i}} + \frac{6(n-4)!}{1^{\alpha_1-2}(\alpha_1-2)! 2^{\alpha_2-1}(\alpha_2-1)! \prod_{i=3}^n \alpha_i! i^{\alpha_i}} + \frac{3(n-4)!}{\alpha_1! 1^{\alpha_1-2} 2^{\alpha_2-2}(\alpha_2-2)! \prod_{i=3}^n \alpha_i! i^{\alpha_i}} + \frac{8(n-4)!}{1^{\alpha_1-1}(\alpha_1-1)! \alpha_2! 2^{\alpha_2-1} \alpha_3^{\alpha_3-1}(\alpha_3-1)! \prod_{i=4}^n \alpha_i! i^{\alpha_i}} + \frac{6(n-4)!}{\alpha_1! 1^{\alpha_1-1} \alpha_2! 2^{\alpha_2-1} \alpha_3! 3^{\alpha_3-1} \alpha_4^{\alpha_4-1}(\alpha_4-1)! \prod_{i=5}^n \alpha_i! i^{\alpha_i}}$$

Proof

Let $\{a, b, c, d\} \in X^{(4)}$ and $g \in A_n$. Then g fixes $\{a, b, c, d\}$ if and only if it permutes the elements in the set $\{a, b, c, d\}$ as in the following cases;

Case 1:

Each of the elements a, b, c and d comes from a single cycle in g . In this case the number of permutations in A_n fixing $\{a, b, c, d\}$ and with the same cycle type as g is equal to the number of permutations of A_{n-4} with cycle type $(\alpha_1-4, \alpha_2, \dots, \alpha_n)$. By Theorem 1.1.13, this number is $\frac{(n-4)!}{(\alpha_1-4)! \prod_{i=2}^n \alpha_i! i^{\alpha_i}}$, for $\alpha_1 \geq 4$.

Case 2:

Two of the elements a, b, c , and d come from single- cycles and the other two elements come from a 2-cycle, say, $(ab)(c)(d) \dots$. In this case the number of permutations in A_n fixing $\{a, b, c, d\}$ and with the same cycle type as g is equal to the number of permutations of A_{n-4} with cycle type $(\alpha_1-2, \alpha_2-1, \alpha_3, \dots, \alpha_n)$. By Theorem 1.1.13 this number is

$$\frac{(n-4)!}{1^{\alpha_1-2}(\alpha_1-2)! 2^{\alpha_2-1}(\alpha_2-1)! \prod_{i=3}^n \alpha_i! i^{\alpha_i}}, \text{ for } \alpha_1 \geq 2 \text{ and } \alpha_2 \geq 1.$$

But the number of ways of filling the blanks $(- -) (-)$ with a, b, c , and d is 6 giving a permutation of the same cycle type as g and fixing $\{a, b, c, d\}$. Therefore the number of permutations in A_n fixing $\{a, b, c, d\}$ and with the same cycle type with g is

$$\frac{6(n-4)!}{1^{\alpha_1-2}(\alpha_1-2)! 2^{\alpha_2-1}(\alpha_2-1)! \prod_{i=3}^n \alpha_i! i^{\alpha_i}}$$

Case 3:

Each of the elements a, b, c, and d come from a 2-cycle in g say (ab)(cd)... In this case the number of permutations in A_n fixing {a, b, c, d} and with the same cycle type as g is equal to the number of permutations of A_{n-4} with cycle type $(\alpha_1, \alpha_2-2, \alpha_3, \dots, \alpha_n)$. By Theorem 1.1.13 this number is $\frac{(n-4)!}{\alpha_1! 1^{\alpha_1} 2^{\alpha_2-2} (\alpha_2-2)! \prod_{i=3}^n \alpha_i! i^{\alpha_i}}$, for $\alpha_2 \geq 2$.

But the number of ways of filling the blanks (- -) (- -) with a, b, c and d is 3, giving a permutation of the same cycle type as g and fixing {a, b, c, d}. Therefore the number of permutations in A_n fixing {a, b, c, d} and with the same cycle type as g is $\frac{3(n-4)!}{\alpha_1! 1^{\alpha_1} 2^{\alpha_2-2} (\alpha_2-2)! \prod_{i=3}^n \alpha_i! i^{\alpha_i}}$.

Case 4:

Three of the elements a, b, c and d come from a 3-cycle and one element comes from a single-cycle say (abc)(d)... In this case the number of permutations in A_n fixing {a, b, c, d} and with the same cycle type as g is equal to the number of permutations of A_{n-4} with cycle type $(\alpha_1-1, \alpha_2, \alpha_3-1, \alpha_4, \dots, \alpha_n)$. By Theorem 1.1.13 this number is

$$\frac{(n-4)!}{1^{\alpha_1-1} (\alpha_1-1)! \alpha_2! 2^{\alpha_2} 3^{\alpha_3-1} (\alpha_3-1)! \prod_{i=4}^n \alpha_i! i^{\alpha_i}}, \text{ for } \alpha_1 \geq 1, \alpha_3 \geq 1.$$

However the number of ways of filling the blanks (- - -)(-) with a, b, c, and d is 8, giving a permutation of the same cycle type as g and fixing {a, b, c, d}. Therefore the number of permutations in A_n fixing {a, b, c, d} and having the same cycle type as g is

$$\frac{8(n-4)!}{1^{\alpha_1-1} (\alpha_1-1)! \alpha_2! 2^{\alpha_2} 3^{\alpha_3-1} (\alpha_3-1)! \prod_{i=4}^n \alpha_i! i^{\alpha_i}}.$$

Case 5:

The elements a, b, c and d come from a 4-cycle of g, say (abcd)... In this case the number of permutations in A_n fixing {a, b, c, d} and with the same cycle type as g is equal to the number of permutations of A_{n-4} with cycle type $(\alpha_1, \alpha_2, \alpha_3, \alpha_4-1, \alpha_5, \dots, \alpha_n)$. By Theorem 1.1.13 this number is $\frac{(n-4)!}{\alpha_1! 1^{\alpha_1} \alpha_2! 2^{\alpha_2} \alpha_3! 3^{\alpha_3} 4^{\alpha_4-1} (\alpha_4-1)! \prod_{i=5}^n \alpha_i! i^{\alpha_i}}$, for $\alpha_4 \geq 1$.

But the number of ways of filling the blanks (- - -) with a,b,c and d is 6, giving a permutation of the same cycle type as g and fixing {a, b, c, d}. Therefore the number of permutations in A_n fixing {a,b,c,d} and having the same cycle type as g is

$$\frac{6(n-4)!}{\alpha_1! 1^{\alpha_1} \alpha_2! 2^{\alpha_2} \alpha_3! 3^{\alpha_3} 4^{\alpha_4-1} (\alpha_4-1)! \prod_{i=5}^n \alpha_i! i^{\alpha_i}}.$$

Therefore the total number of permutations in A_n that fix {a, b, c, d} $\in X^{(4)}$ and with the same cycle type as g is the sum of the formulas in the five cases which yield the given formula. ■

2.2 Some properties of the alternating group $A_n(n \leq 7)$ acting on unordered quadruples

Theorem 2.2.1

$G=A_4$ acts transitively on $X^{(4)}$.

Proof

We can prove this by using the Cauchy-Frobenius Lemma (Theorem 1.1.15). Let $g \in A_4$ have cycle type $(\alpha_1, \alpha_2, \alpha_3, \alpha_4)$, then the number of permutations in A_4 having the same cycle type as g is given by Theorem 1.1.13 and the number of elements in $X^{(4)}$ fixed by each $g \in A_4$ is given by Lemma 2.1.1. We now have the following Table

Table 2.2.1: Permutations in A_4 and number of fixed points

Permutations in A_4	Cycle type	Number of permutations	$ \text{Fix}(g) $ in $X^{(4)}$
1	(4,0,0,0)	1	1
(abc)	(1,0,1,0)	8	1
(ab)(cd)	(0,2,0,0)	3	1

By Cauchy-Frobenius Lemma, we get the number of the orbits of A_4 acting on $X^{(4)}$,

$$\frac{1}{|A_4|} \sum_{g \in A_4} |\text{Fix}(g)| = \frac{1}{12} [(1 \times 1) + (8 \times 1) + (3 \times 1)] = \frac{12}{12} = 1$$

This implies that A_4 acts transitively on $X^{(4)}$.

Alternatively we can use the Orbit-Stabilizer Theorem (Theorem 1.1.14). In this case we have to show that the length of the orbit of a point say $\{1,2,3,4\}$ in $X^{(4)}$ is 1, the same as the number of points in $X^{(4)}$. Now let $g \in A_4$ have cycle type $(\alpha_1, \alpha_2, \alpha_3, \alpha_4)$, then the number of permutations in A_4 fixing $\{1,2,3,4\}$ and having the same cycle type as g is given by Lemma 2.1.2.

We now have the following Table;

Table 2.2.2: Number of permutations in $G=A_4$ fixing $\{1,2,3,4\}$

Permutation in A_4	Cycle type	Number fixing $\{1,2,3,4\}$
1	(4,0,0,0)	1
(abc)	(1,0,1,0)	8
(ab)(cd)	(0,2,0,0)	3
Total		12

From the table $|G_{\{1,2,3,4\}}|=12$.

Therefore by Orbit-Stabilizer Theorem,

$$\begin{aligned} |\text{Orb}_G \{1, 2, 3, 4\}| &= |G : \text{Stab}_G \{1, 2, 3, 4\}| \\ &= \frac{|G|}{|\text{Stab}_G \{1, 2, 3, 4\}|} \\ &= \frac{12}{12} = 1 = |X^{(4)}|. \end{aligned}$$

Hence the orbit of $\{1,2,3,4\}$ is the whole of $X^{(4)}$ and therefore A_4 acts transitively on $X^{(4)}$. ■

Theorem 2.2.2

$G=A_5$ acts transitively on $X^{(4)}$.

Proof

We can prove this by Cauchy-Frobenius Lemma (Theorem 1.1.15). Let $g \in A_5$ have cycle type

$(\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5)$, then the number of permutations in A_5 having the same cycle type as g is given by Theorem 1.1.13 and the number of elements in $X^{(4)}$ fixed by each $g \in A_5$ is given by Lemma 2.1.1. We now have the following Table;

Table 2.2.3: Permutations in A_5 and number of fixed points

Permutations in A_5	Cycle type	Number of permutations	$ \text{Fix}(g) $ in $X^{(4)}$
1	(5,0,0,0,0)	1	5
(abc)	(2,0,1,0,0)	20	2
(ab)(cd)	(1,2,0,0,0)	15	1
(abcde)	(0,0,0,0,1)	24	0

By Cauchy Frobenius Lemma, we get the number of the orbits of A_5 acting on $X^{(4)}$,

$$\frac{1}{|A_5|} \sum_{g \in A_5} |\text{Fix}(g)| = \frac{1}{60} [(1 \times 5) + (20 \times 2) + (15 \times 1) + (24 \times 0)]$$

$$= \frac{60}{60} = 1.$$

This implies that A_5 acts transitively on $X^{(4)}$.

Alternatively we can use the Orbit-Stabilizer Theorem (Theorem 1.1.12). In this case we have to show that the length of the orbit of a point say $\{1,2,3,4\}$ in $X^{(4)}$ is 5, the same as the number of points in $X^{(4)}$. Let $g \in A_5$ have cycle type $(\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5)$, then the number of permutations in A_5 fixing $\{1,2,3,4\}$ and having the same cycle type as g is given by Lemma 2.1.2. We now have the following Table;

Table 2.2.4: Number of permutations in $G=A_5$ fixing $\{1,2,3,4\}$

Permutation in A_5	Cycle type	Number fixing $\{1,2,3,4\}$
1	(5,0,0,0,0)	1
(abc)	(2,0,1,0,0)	8
(ab)(cd)	(1,2,0,0,0)	3
(abcd)	(0,0,0,0,1)	0
Total		12

From the table $|G_{\{1,2,3,4\}}|=12$.

Therefore by Orbit-Stabilizer Theorem,

$$|\text{Orb}_G \{1, 2, 3, 4\}| = |G : \text{Stab}_G \{1, 2, 3, 4\}|$$

$$= \frac{|G|}{|\text{Stab}_G \{1,2,3,4\}|}$$

$$= \frac{60}{12} = 5 = |X^{(4)}|.$$

Hence the orbit of $\{1,2,3,4\}$ is the whole of $X^{(4)}$ and therefore A_5 acts transitively on $X^{(4)}$. ■

Theorem 2.2.3

A_5 does not act doubly transitively on $X^{(4)}$

Proof

Given any two pair of points say $\{1, 2, 3, 4\}, \{1, 2, 3, 5\} \in X^{(4)}$ and $\{1, 2,4,5\}, \{1, 5, 3, 4\} \in X^{(4)}$ and suppose that there exists a permutation $g \in A_5$ such that $g[\{1, 2, 3, 4\}, \{1, 2, 3, 5\}] = [\{1, 2, 4, 5\}, \{1, 5, 3, 4\}]$; then $g \{1, 2, 3,$

$4) = \{g(1), g(2), g(3), g(4)\} = \{1, 2, 4, 5\}$ and $g\{1, 2, 3, 5\} = \{g(1), g(2), g(3), g(5)\} = \{1, 5, 3, 4\}$. Implying that $g(2)=2$ and $g(2)=5$, this is impossible. Thus A_5 does not act doubly transitively on $X^{(4)}$. ■

Theorem 2.2.4 $G=A_6$ acts transitively on $X^{(4)}$.

Proof

We will prove this by Cauchy-Frobenius Lemma (Theorem 1.1.15). Let $g \in A_6$ have cycle type $(\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5, \alpha_6)$, then the number of permutations in A_6 having the same cycle type as g is given by Theorem 1.1.13 and the number of elements in $X^{(4)}$ fixed by each $g \in A_6$ is given by Lemma 2.1.1. We now have the following

Table 2.2.5: Permutations in A_6 and number of fixed points

Permutations in A_6	Cycle type	Number of permutations	$ \text{Fix}(g) $ in $X^{(4)}$
1	(6,0,0,0,0,0)	1	360
(abc)	(3,0,1,0,0,0)	40	0
(ab)(cd)	(2,2,0,0,0,0)	45	0
(abcde)	(1,0,0,0,1,0)	144	0
(ab)(cdef)	(0,1,0,1,0,0)	90	0
(abc)(def)	(0,0,2,0,0,0)	40	0

By Cauchy-Frobenius Lemma, we get the number of the orbits of A_6 acting on $X^{(4)}$,

$$\frac{1}{|A_6|} \sum_{g \in A_6} |\text{Fix}(g)| = \frac{1}{360} [(1 \times 360) + (0 \times 40) + (0 \times 144) + (0 \times 45) + (0 \times 90) + (0 \times 40)] = \frac{360}{360} = 1.$$

This implies that A_6 acts transitively on $X^{(4)}$.

Alternatively we can use the Orbit-Stabilizer Theorem (Theorem 1.1.14). In this case we have to show that the length of the orbit of a point say $\{1,2,3,4\}$ in $X^{(4)}$ is 15, the same as the number of points in $X^{(4)}$. Let $g \in A_6$ have cycle type $(\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5, \alpha_6)$, then the number of permutations in A_6 fixing $\{1,2,3,4\}$ and having the same cycle type as g is given by Lemma 2.1.2.

We now have the following Table;

Table 2.2.6: Number of permutations in $G=A_6$ fixing $\{1,2,3,4\}$

Permutation in A_6	Cycle type	Number fixing $\{1,2,3,4\}$
1	(6,0,0,0,0,0)	1
(abc)	(3,0,1,0,0,0)	8
(ab)(cd)	(2,2,0,0,0,0)	9
(abcde)	(1,0,0,0,1,0)	0
(ab)(cdef)	(0,1,0,1,0,0)	6
(abc)(def)	(0,0,2,0,0,0)	0
Total		24

From the table $|G_{\{1,2,3,4\}}| = 24$.

Therefore by Orbit-Stabilizer Theorem,

$$|\text{Orb}_G \{1, 2, 3, 4\}| = |G : \text{Stab}_G \{1, 2, 3, 4\}|$$

$$= \frac{|G|}{|\text{Stab}_G \{1, 2, 3, 4\}|}$$

$$= \frac{360}{24} = 15 = |X^{(4)}|.$$

Hence the orbit of $\{1, 2, 3, 4\}$ is the whole of $X^{(4)}$ and therefore A_6 acts transitively on $X^{(4)}$. ■

Theorem 2.2.5

A_6 does not act doubly transitively on $X^{(4)}$.

Proof

Given any two pair of points say $\{1, 2, 3, 4\}, \{1, 2, 3, 5\} \in X^{(4)}$ and $\{1, 2, 4, 6\}, \{1, 6, 3, 4\} \in X^{(4)}$ and suppose that there exists a permutation $g \in A_6$ such that $g[\{1, 2, 3, 4\}, \{1, 2, 3, 5\}] = [\{1, 2, 4, 6\}, \{1, 6, 3, 4\}]$; then $g\{1, 2, 3, 4\} = \{g(1), g(2), g(3), g(4)\} = \{1, 2, 4, 6\}$ and $g\{1, 2, 3, 5\} = \{g(1), g(2), g(3), g(5)\} = \{1, 6, 3, 4\}$. Implying that $g(2)=2$ and $g(2)=6$, this is impossible. Thus A_6 does not act doubly transitively on $X^{(4)}$. ■

Theorem 2.2.6

$G=A_7$ acts transitively on $X^{(4)}$.

Proof

We can prove this by Cauchy-Frobenius Lemma (Theorem 1.1.15). Let $g \in A_7$ have cycle type $(\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5, \alpha_6, \alpha_7)$, then the number of permutations in A_7 having the same cycle type as g is given by Theorem 1.1.13 and the number of elements in $X^{(4)}$ fixed by each $g \in A_7$ is given by Lemma 2.1.1. We now have the following Table;

Table 2.2.7: Permutations in A_7 and the number of fixed points

Permutation g in A_7	Cycle type	Number of permutations	$ \text{Fix}(g) $ in $X^{(4)}$
1	(7,0,0,0,0,0,0)	1	35
(abc)	(4,0,1,0,0,0,0)	70	5
(abcde)	(2,0,0,0,1,0,0)	504	0
(abcdefg)	(0,0,0,0,0,0,1)	720	0
(ab)(cdef)	(1,1,0,1,0,0,0)	630	1
(ab)(cd)	(3,2,0,0,0,0,0)	105	7
(ab)(cd)(efg)	(0,2,1,0,0,0,0)	210	1
(abc)(def)	(1,0,2,0,0,0,0)	280	2

By Cauchy-Frobenius Lemma we get the number of the orbits of A_7 acting on $X^{(4)}$,

$$\frac{1}{|A_7|} \sum_{g \in A_7} |\text{Fix}(g)| = \frac{1}{2520} [(35 \times 1) + (5 \times 70) + (0 \times 504) + (0 \times 720) + (1 \times 630) + (7 \times 105) + (1 \times 210) + (2 \times 280)]$$

$$= \frac{1}{2520} [35 + 350 + 630 + 735 + 210 + 560]$$

$$= \frac{2520}{2520} = 1.$$

This implies that A_7 acts transitively on $X^{(4)}$.
 Alternatively we can use the Orbit-Stabilizer Theorem (Theorem 1.1.14). In this case we have to show that the length of the orbit of a point say $\{1, 2, 3, 4\}$ in $X^{(4)}$ is 35, the same as the number of points in $X^{(4)}$. Let $g \in A_7$ have a cycle type $(\alpha_1, \alpha_2, \dots, \alpha_n)$, the number of permutations in A_7 fixing $\{1, 2, 3, 4\}$ and having the same cycle type as g is given by Lemma 2.1.2. We now have the following Table;

Table 2.2.8: Number of permutations in $G=A_7$ fixing $\{1, 2, 3, 4\}$

Permutation g in A_7	Cycle type	Number fixing $\{1,2,3,4\}$
1	(7,0,0,0,0,0,0)	1
(abc)	(4,0,1,0,0,0,0)	10
(abcde)	(2,0,0,0,1,0,0)	0
(abcdefg)	(0,0,0,0,0,0,1)	0
(ab)(cdef)	(1,1,0,1,0,0,0)	18
(ab)(cd)	(3,2,0,0,0,0,0)	21
(ab)(cd)(efg)	(0,2,1,0,0,0,0)	6
(abc)(def)	(1,0,2,0,0,0,0)	16
Total		72

From the table $|G_{\{1,2,3,4\}}|=72$.

Therefore by Orbit-Stabilizer Theorem,

$$\begin{aligned}
 |\text{Orb}_G \{1, 2, 3, 4\}| &= |G : \text{Stab}_G \{1, 2, 3, 4\}| \\
 &= \frac{|G|}{|\text{Stab}_G \{1,2,3,4\}|} \\
 &= \frac{2520}{72} = 35 = |X^{(4)}|.
 \end{aligned}$$

Hence the orbit of $\{1, 2, 3, 4\}$ is the whole of $X^{(4)}$ and therefore A_7 acts transitively on $X^{(4)}$. ■

Does not act doubly transitively on $X^{(4)}$.

Proof

Given any two pair of points say $\{1, 2, 3, 4\}, \{1, 2, 3, 5\} \in X^{(4)}$ and $\{1, 2, 3, 6\}, \{1, 7, 3, 4\} \in X^{(4)}$ and suppose that there exists a permutation $g \in A_7$ such that $g[\{1, 2, 3, 4\}, \{1, 2, 3, 5\}] = [\{1, 2, 3, 6\}, \{1, 7, 3, 4\}]$; then $g\{1, 2, 3, 4\} = \{g(1), g(2), g(3), g(4)\} = \{1, 2, 3, 6\}$ and $g\{1, 2, 3, 5\} = \{g(1), g(2), g(3), g(5)\} = \{1, 7, 3, 4\}$. Implying that $g(2)=2$ and $g(2)=7$, this is impossible. Thus A_7 does not act doubly transitively on $X^{(4)}$. ■

3.ACTIONS OF THE ALTERNATING GROUP A_n ON ORDERED QUADRUPLES

3.1 some general results of permutation groups acting on $X[4]$

Similarly like in section 2.1 we give the proofs of two lemmas which will be very useful in the investigation of transitivity of the action of A_n on $X[4]$

Lemma 2.1.3

Let $g \in A_n$ be a permutation with cycle type $(\alpha_1, \alpha_2, \dots, \alpha_n)$. Then $|\text{Fix}(g)|$ in $X^{[4]}$ is given by the formula

$$4! \binom{\alpha_1}{4}.$$

Proof

Let $[a,b,c,d] \in X^{[4]}$ and $g \in A_n$. Then g fixes $[a,b,c,d]$ if and only if each of the elements a,b,c,d are mapped onto themselves, that is, $g[a,b,c,d]=[g(a),g(b),g(c),g(d)]=[a,b,c,d]$ implying $ga=a, gb=b, gc=c$ and $gd=d$. Thus each of a,b,c and d comes from single cycles. Therefore the number of unordered quadruples fixed by $g \in A_n$ is

$$\binom{\alpha_1}{4}.$$

But unordered quadruple, can be rearranged to give $24=4!$ distinct ordered quadruples. Thus the number of ordered quadruples fixed by $g \in A_n$ is

$$4! \binom{\alpha_1}{4}. \quad \blacksquare$$

Lemma 2.1.4

Let $g \in A_n$ be a permutation with cycle type $(\alpha_1, \alpha_2, \dots, \alpha_n)$. Then the number of permutations in A_n fixing $[a,b,c,d] \in X^{[4]}$ and having the same cycle type as g is given by

$$\frac{(n-4)!}{(\alpha_1-4)! 1^{\alpha_1-4} \prod_{i=2}^n \alpha_i! i^{\alpha_i}}, \text{ for } \alpha_1 \geq 4.$$

Proof

Let $g \in A_n$ have cycle type $(\alpha_1, \alpha_2, \dots, \alpha_n)$ and let g fix $[a,b,c,d]$. Then each of a,b,c and d must come from a single cycle in g . Thus to count the number of permutations in A_n having the the same cycle types as g and fixing a,b,c and d is the same as counting the number of permutations in A_{n-4} having cycle type $(\alpha_1-4, \alpha_2, \dots, \alpha_n)$. By Theorem 1.1.13 this number is

$$\frac{(n-4)!}{(\alpha_1-4)! 1^{\alpha_1-4} \prod_{i=2}^n \alpha_i! i^{\alpha_i}}, \text{ for } \alpha_1 \geq 4. \quad \blacksquare$$

.3 Some properties of the alternating groups A_n ($n \leq 7$) acting on $X^{[4]}$

Theorem 2.3.1 $G=A_6$ acts transitively on $X^{[4]}$.

Proof

We can prove this by the use of Cauchy-Frobenius Lemma (Theorem 1.1.15). Let $g \in A_6$ have cycle type $(\alpha_1, \alpha_2, \dots, \alpha_6)$, then the number of permutations in A_6 having the same cycle type as g is given by Theorem 1.1.13 and the number of elements in $X^{[4]}$ fixed by g is given by Lemma 2.1.3. We now have the following Table;

Table 2.3.1: Permutations in A_6 and the number of fixed points

Permutation in A_6	Cycle type	Number of permutations	$ \text{Fix}(g) $ in $X^{[4]}$
1	(6,0,0,0,0,0)	1	360
(abc)	(3,0,1,0,0,0)	40	0
(abcde)	(1,0,0,0,1,0)	144	0
(ab)(cd)	(2,2,0,0,0,0)	45	0
(ab)(cdef)	(0,1,0,1,0,0)	90	0
(abc)(def)	(0,0,2,0,0,0)	40	0

By Cauchy-Frobenius Theorem we get the number of the orbits of A_6 acting on $X^{[4]}$,

$$\begin{aligned} \frac{1}{|A_6|} \sum_{g \in A_6} |\text{Fix}(g)| &= \frac{1}{360} [(360 \times 1) + (0 \times 40) + (0 \times 144) + (0 \times 45) + (0 \times 90) + (0 \times 40)] \\ &= \frac{360}{360} = 1. \end{aligned}$$

This implies that A_6 acts transitively on $X^{[4]}$. ■

Alternatively we can use the Orbit-Stabilizer Theorem (Theorem 1.1.14). In this case we have to show that the length of the orbit of a point say $[1, 2, 3, 4]$ in $X^{[4]}$ is 360, the same as the number of points in $X^{[4]}$. Let $g \in A_6$ have cycle type $(\alpha_1\alpha_2, \dots, \alpha_6)$, then the number of permutations in A_6 fixing $[1, 2, 3, 4]$ and having the same cycle type as g is given by Lemma 2.1.4. We now have the following Table;

Table 2.3.2: Number of permutations in $G=A_6$ fixing $[1, 2, 3, 4]$

Permutation in A_6	Cycle type	Number fixing $[1,2,3,4]$
1	(6,0,0,0,0,0)	1
(abc)	(3,0,1,0,0,0)	0
(abcde)	(1,0,0,0,1,0)	0
(ab)(cd)	(2,2,0,0,0,0)	0
(ab)(cdef)	(0,1,0,1,0,0)	0
(abc)(def)	(0,0,2,0,0,0)	0

By Orbit-Stabilizer Theorem,

$$\begin{aligned}
 |\text{Orb}_G [1, 2, 3, 4]| &= |G: \text{Stab}_G [1, 2, 3, 4]| \\
 &= \frac{|G|}{|\text{Stab}_G [1,2,3,4]|} = \frac{360}{1} \\
 &= 360 = |X^{[4]}|.
 \end{aligned}$$

Hence the orbit of $[1, 2, 3, 4]$ is the whole of $X^{[4]}$ and therefore A_6 acts transitively on $X^{[4]}$. ■

Theorem 2.3.2

$G=A_6$ does not act doubly transitively on $X^{[4]}$.

Proof

Given any two pair of points say $[1, 2, 3, 4], [1, 2, 4, 5] \in X^{[4]}$ and $[1, 2, 3, 6], [1, 6, 3, 4] \in X^{[4]}$ and suppose that there exists a permutation $g \in A_6$ such that $g[[1, 2, 3, 4], [1, 2, 4, 5]] = [[1, 2, 3, 6], [1, 6, 3, 4]]$; then $g [1, 2, 3, 4] = [g(1), g(2), g(3), g(4)] = [1, 2, 3, 6]$ and $g [1, 2, 3, 5] = [g(1), g(2), g(3), g(5)] = [1, 6, 3, 4]$. Implying that $g(2)=2$ and $g(2)=6$, this is impossible. Thus A_6 does not act doubly transitively on $X^{[4]}$. ■

Theorem 2.3.3

$G=A_7$ acts transitively on $X^{[4]}$.

Proof

We can prove this by the use of Cauchy–Frobenius Lemma (Theorem 1.1.15). Let $g \in A_7$ have cycle type $(\alpha_1, \alpha_2, \dots, \alpha_7)$, then the number of permutations in A_7 having the same cycle type as g is given by Theorem 1.1.13 and the number of elements in $X^{[4]}$ fixed by g is given by Lemma 2.1.3. We now have the following Table;

Table 2.3.3: Permutations in A_7 and the number of fixed points

Permutation g in A_7	Cycle type	Number of permutations	$ \text{Fix}(g) $ in $X^{[4]}$
1	(7,0,0,0,0,0,0)	1	840
(abc)	(4,0,1,0,0,0,0)	70	24
(abcde)	(2,0,0,0,1,0,0)	504	0
(abcdefg)	(0,0,0,0,0,0,1)	720	0
(ab)(cdef)	(1,1,0,1,0,0,0)	630	0
(ab)(cd)	(3,2,0,0,0,0,0)	105	0
(ab)(cd)(efg)	(0,2,1,0,0,0,0)	210	0
(abc)(def)	(1,0,2,0,0,0,0)	280	0

By Cauchy-Frobenius Lemma we get the number of the orbits of A_7 acting on $X^{[4]}$,

$$\begin{aligned} & \frac{1}{|A_7|} \sum_{g \in A_7} |\text{Fix}(g)| \\ &= \frac{1}{2520} [(840 \times 1) + (24 \times 70) + (0 \times 504) + (0 \times 720) + (0 \times 630) + \\ & \quad (0 \times 210) + (0 \times 280)] \\ &= \frac{1}{2520} [840 + 1680 + 0 + 0 + 0 + 0 + 0] \\ &= \frac{2520}{2520} = 1. \end{aligned} \tag{0 \times 105} +$$

This implies that A_7 acts transitively on $X^{[4]}$.

Alternatively we can use the Orbit-Stabilizer Theorem (Theorem 1.1.14). In this case we have to show that the length of the orbit of a point say $[1, 2, 3, 4]$ in $X^{[4]}$ is 840, the same as the number of points in $X^{[4]}$. Let $g \in A_n$ have cycle type $(\alpha_1 \alpha_2 \dots \alpha_r)$, then number of permutations in A_7 fixing $[1, 2, 3, 4]$ and having the same cycle type as g is given by Lemma 2.1.4. We now have the following Table;

Table 2.3.4: Number of permutations in $G=A_7$ fixing $[1, 2, 3, 4]$

Permutation g in A_7	Cycle type	Number fixing $[1,2,3,4]$
1	(7,0,0,0,0,0,0)	1
(abc)	(4,0,1,0,0,0,0)	2
(abcde)	(2,0,0,0,1,0,0)	0
(abcdefg)	(0,0,0,0,0,0,1)	0
(ab)(cdef)	(1,1,0,1,0,0,0)	0
(ab)(cd)	(3,2,0,0,0,0,0)	0
(ab)(cd)(efg)	(0,2,1,0,0,0,0)	0
(abc)(def)	(1,0,2,0,0,0,0)	0
Total		3

By Orbit-Stabilizer Theorem,

$$\begin{aligned} |\text{Orb}_G [1, 2, 3, 4]| &= |G : \text{Stab}_G [1, 2, 3, 4]| \\ &= \frac{|G|}{|\text{Stab}_G [1,2,3,4]|} = \frac{2520}{3} \\ &= 840 = |X^{[4]}|. \end{aligned}$$

Hence the orbit of $[1, 2, 3, 4]$ is the whole of $X^{[4]}$ and therefore A_7 acts transitively on $X^{[4]}$. ■

Theorem 2.3.4

$G=A_7$ does not act doubly transitively on $X^{[4]}$.

Proof

Given any two pair of points say $[1, 2, 3, 4], [1, 2, 4, 7] \in X^{[4]}$ and $[1, 2, 3, 5], [1, 7, 3, 4] \in X^{[4]}$ and suppose that there exists a permutation $g \in A_7$ such that $g[[1, 2, 3, 4], [1, 2, 4, 7]]$

$= [[1, 2, 3, 5], [1, 7, 3, 4]]$; then $g [1, 2, 3, 4] = [g(1), g(2), g(3), g(4)] = [1, 2, 3, 5]$ and $g [1, 2, 4, 7] = [g(1), g(2), g(3), g(7)] = [1, 7, 3, 4]$. Implying that $g(2)=2$ and $g(2)=7$, this is impossible. Thus A_7 does not act doubly transitively on $X^{[4]}$. ■

Therefore G acts transitively on $X^{[4]}$

Conclusion: This implies that A_n (for $n \leq 7$) acts transitively on $X^{(4)}$ and $X^{[4]}$
